## English (eng), day 1

Problem 1. Let $\mathbb{Z}$ be the set of integers. Determine all functions $f: \mathbb{Z} \rightarrow \mathbb{Z}$ such that, for all integers $a$ and $b$,

$$
f(2 a)+2 f(b)=f(f(a+b)) .
$$

Problem 2. In triangle $A B C$, point $A_{1}$ lies on side $B C$ and point $B_{1}$ lies on side $A C$. Let $P$ and $Q$ be points on segments $A A_{1}$ and $B B_{1}$, respectively, such that $P Q$ is parallel to $A B$. Let $P_{1}$ be a point on line $P B_{1}$, such that $B_{1}$ lies strictly between $P$ and $P_{1}$, and $\angle P P_{1} C=\angle B A C$. Similarly, let $Q_{1}$ be a point on line $Q A_{1}$, such that $A_{1}$ lies strictly between $Q$ and $Q_{1}$, and $\angle C Q_{1} Q=\angle C B A$.

Prove that points $P, Q, P_{1}$, and $Q_{1}$ are concyclic.
Problem 3. A social network has 2019 users, some pairs of whom are friends. Whenever user $A$ is friends with user $B$, user $B$ is also friends with user $A$. Events of the following kind may happen repeatedly, one at a time:

Three users $A, B$, and $C$ such that $A$ is friends with both $B$ and $C$, but $B$ and $C$ are not friends, change their friendship statuses such that $B$ and $C$ are now friends, but $A$ is no longer friends with $B$, and no longer friends with $C$. All other friendship statuses are unchanged.

Initially, 1010 users have 1009 friends each, and 1009 users have 1010 friends each. Prove that there exists a sequence of such events after which each user is friends with at most one other user.

Problem 4. Find all pairs $(k, n)$ of positive integers such that

$$
k!=\left(2^{n}-1\right)\left(2^{n}-2\right)\left(2^{n}-4\right) \cdots\left(2^{n}-2^{n-1}\right)
$$

Problem 5. The Bank of Bath issues coins with an $H$ on one side and a $T$ on the other. Harry has $n$ of these coins arranged in a line from left to right. He repeatedly performs the following operation: if there are exactly $k>0$ coins showing $H$, then he turns over the $k^{\text {th }}$ coin from the left; otherwise, all coins show $T$ and he stops. For example, if $n=3$ the process starting with the configuration THT would be THT $\rightarrow H H T \rightarrow H T T \rightarrow T T T$, which stops after three operations.
(a) Show that, for each initial configuration, Harry stops after a finite number of operations.
(b) For each initial configuration $C$, let $L(C)$ be the number of operations before Harry stops. For example, $L(T H T)=3$ and $L(T T T)=0$. Determine the average value of $L(C)$ over all $2^{n}$ possible initial configurations $C$.

Problem 6. Let $I$ be the incentre of acute triangle $A B C$ with $A B \neq A C$. The incircle $\omega$ of $A B C$ is tangent to sides $B C, C A$, and $A B$ at $D, E$, and $F$, respectively. The line through $D$ perpendicular to $E F$ meets $\omega$ again at $R$. Line $A R$ meets $\omega$ again at $P$. The circumcircles of triangles $P C E$ and $P B F$ meet again at $Q$.
Prove that lines $D I$ and $P Q$ meet on the line through $A$ perpendicular to $A I$.
